Engagement & Cost Structure

Outcome-Aligned System Stability & Domain Enforcement

Metatron Dynamics

Robin Macomber, Founder · Bruce Stephenson, CTO — Energy Physics

relationalrelativity.dev · github.com/Relational-Relativity-Corporation

I. ENGAGEMENT PHILOSOPHY

We de-risk adoption by tying our upside to your results

Metatron Dynamics does not ask clients to believe in the framework before committing budget. The engagement is structured so that the majority of our compensation is tied to measurable system improvements — verified cost savings, avoided losses, and documented stability gains.

The tools we deploy are not the product. They are the entry point. They expose domain violations inside your system in a form that is directly observable. The tooling is fully functional; however, correct deployment, configuration, and interpretation require synchronous engagement with Metatron Dynamics. The tools are not offered as standalone products at this stage. The product is the application of domain declaration and operator enforcement to eliminate those violations before they propagate into cost.

This requirement reflects a broader condition across modern systems: complexity has exceeded the capacity of human cognition and oversight to reliably maintain bounded operation. Without explicit structural scaffolding, systems drift into undeclared or unbounded behavior. Correct domain definition, calibration, and enforcement therefore cannot be assumed — they must be applied explicitly and in context.

> *We apply the framework to your system, measure the result, and participate in the value created. If the value is not there, the majority of our compensation is not there.*

TRADITIONAL CONSULTING	METATRON DYNAMICS MODEL
Fixed fee regardless of outcome	Base fee covers access and assessment only
Deliverable is a report or recommendation	Deliverable is measurable system improvement
Implementation risk stays with client	Performance participation aligns our upside with yours
No structural alignment with results	We remain engaged until violations are resolved

II. ENGAGEMENT PHASES & COST STRUCTURE

Four phases. One continuous engagement.

The engagement is structured as a sequential deployment — each phase builds on the previous. Pricing ranges reflect system complexity and organizational scale. All figures are indicative; final structure is agreed prior to engagement.

PHASE 1 Domain Assessment & Tool Deployment — $15,000 – $35,000

Low-friction entry point. We deploy the open tooling against a defined subsystem and produce the first structural domain map. Client sees hidden violations in their own system before committing further.

- Deploy md-domain-verifier against target subsystem
- Run md-pipeline A→E verification pass
- Identify undeclared relations and boundary violations
- Deploy md-runtime-guard with domain bounds configured through synchronous engagement with Metatron Dynamics
- Map implicit domain assumptions in existing code or models
- Deliver written Domain Assessment Report

PHASE 2 Baseline Measurement & Operator Application — $25,000 – $60,000

The ABRCE kernel is calibrated to the client's specific system geometry. Agreed performance metrics are baselined. First structural early warning signal is produced against live or production-representative data.

- Capture current system behavior across agreed metrics
- Apply full A→B→R→C→E operator sequence to client domain
- Establish verified baseline for performance participation
- Calibrate ρ to client relational structure
- Define measurable performance targets (downtime, error rate, throughput)
- Deliver Baseline Measurement Report with agreed KPIs

PHASE 3 Integration & Synchronous Enforcement — $40,000 – $120,000

The enforcement layer operates through direct, synchronous engagement with the system and its operators. This is not optional — correct domain enforcement depends on real-time interaction with system conditions and intent.

- Embed md-pipeline into CI/CD or operational pipeline
- Synchronous engagement with system operators during integration
- Connect to monitoring dashboards and alerting infrastructure
- Configure runtime boundary enforcement for production
- Interpret and resolve violation signals in operational context
- Deliver Integration Verification Report

PHASE 4 Capability Transfer — $20,000 – $50,000

Internal teams are trained in domain declaration and operator application. The client develops durable internal capacity — the perspective shift becomes an organizational asset that compounds independently of continued Metatron Dynamics involvement.

- Domain declaration training for engineering leads
- Internal runbook for ongoing enforcement maintenance
- Operator calibration protocol documentation
- Handoff of all tooling configuration and parameterization

$100K
Minimum full engagement
(small system, lower complexity)

$265K
Maximum base fee range
(large system, full integration)

+Performance
Majority of Metatron upside tied to verified results

III. PERFORMANCE PARTICIPATION

Our upside is tied to your measurable improvement

The base engagement fee covers access, assessment, integration, and transfer. The majority of Metatron Dynamics compensation is structured as performance participation — tied to verified, agreed metrics measured against the Phase 2 baseline.

Metric Category	Example Measure	Participation Structure
Downtime Reduction	Unplanned outage hours eliminated vs. baseline	15–25% of verified avoided cost, measured over 12 months
Error Rate Reduction	Domain violation events per 10,000 executions	Fixed per-point improvement fee against agreed baseline rate
Compute Efficiency	Redundant execution cycles eliminated	10–20% of documented infrastructure cost reduction

Metric Category	Example Measure	Participation Structure
Throughput Improvement	Units processed per period vs. baseline	Revenue participation on incremental throughput above threshold
Avoided Loss	Cascade failures prevented, supply chain events avoided	15–30% of verified avoided loss, documented against prior incident rate

Participation rates and measurement windows are agreed in writing prior to Phase 2. All measurement is conducted against the independently established Phase 2 baseline. No participation is claimed for improvements that cannot be directly attributed to the engagement.

> *The performance participation structure exists because we are confident the improvements are real. If they are not, the majority of our compensation is not triggered.*

IV. ILLUSTRATIVE SCENARIOS

What the economics look like in practice

SCENARIO A — MID-SIZE SOFTWARE ORGANIZATION

Phase 1 — Domain Assessment	$22,000
Phase 2 — Baseline & Operator Application	$38,000
Phase 3 — CI/CD Integration	$55,000
Phase 4 — Capability Transfer	$28,000
Base Fee Total	$143,000
Performance Participation (12-month, 20% of $800K avoided downtime cost)	$160,000
Total Engagement Value (Metatron)	**$303,000**

SCENARIO B — MANUFACTURING / INDUSTRIAL SYSTEM

Phase 1 — Domain Assessment	$35,000
Phase 2 — Baseline & Operator Application	$60,000
Phase 3 — Production Integration	$120,000
Phase 4 — Capability Transfer	$45,000

Base Fee Total	$260,000
Performance Participation (12-month, 25% of $3.2M avoided cascade losses)	$800,000
Total Engagement Value (Metatron)	**$1,060,000**

Scenarios are illustrative. Actual figures depend on system scope, complexity, and agreed performance metrics. Performance participation is subject to independent verification.

V. WHY THIS IS DEFENSIBLE

The value is in application, not in the operators themselves

The ABRCE framework is formally defined, openly expressed, and publicly verifiable. The operators are not proprietary. The defensibility of the business model does not rest on secrecy.

The economic value is in correct application within real systems. The tooling provides visibility into structural violations; the value is realized through correct interpretation and resolution within the live system context.

Capability	Why It Is Difficult to Replicate
System-specific domain mapping	Every system has a different implicit domain. Mapping it requires direct engagement with the system, its operators, and its failure history — not a framework alone.
Relational parameterization	Calibrating ρ to a specific system geometry requires understanding of the system's relational structure. This is nontrivial and context-dependent.
Violation interpretation	A structural violation signal is not self-interpreting. Understanding what it means in the context of a live system requires domain expertise and synchronous engagement.
Production integration	Embedding enforcement into operational infrastructure requires navigating the client's specific tooling, constraints, and organizational context.

> *The open tools create trust. The application layer creates value. Neither exists without the other.*
